PRINT DRAWER · RASTERIZE ONCE

Flip the paper. Skip the wait.

The Print drawer now rasterizes each slide **once** and caches the images. Changing paper or orientation re-places those images onto the new sheet — no re-rasterize.

WHY IT WAS SLOW

A paper change used to rebuild the whole PDF.

- Every Letter-to-Legal-to-A4 flip re-ran the expensive step: **clone, embed fonts, rasterize** each slide.
- On a chart-heavy deck that is the dominant cost — paid again on every toggle.
- The pixels never changed, though — only where they land on the page did.

Rasterize and assemble are now two steps.

Rasterize

Each slide becomes a self-contained image at its native box, cached by render — not by paper.

Assemble

Place the cached images on the chosen sheet: pure geometry, fit and centered.

WHAT THE FLIP COSTS NOW

Re-place is a fraction of a rebuild.

1×	**0**	**3**	**2**
RASTERIZE PER DECK	RE-RASTERIZES PER FLIP	PAPER SIZES REUSE IT	ORIENTATIONS REUSE IT

The cache key is the render, not the sheet.

Paper size

Re-places from cache — Letter, Legal, and A4 reuse the same images.

Orientation

Re-places from cache — landscape and portrait share the pixels.

Color mode

Re-renders — black & white is new ink, so the cache drops.

One tap

Desktop still prints the vector deck in a single click.

ONE SOURCE OF TRUTH

The drawer and the CLI assemble the same way.

- `rasterizeDeckImages` and `assembleSheetPdf` live in the shared print kernel.
- The Print drawer caches images across flips; a Node export calls the same halves.
- `fitSlideOnSheet` places every slide — so the two surfaces can never disagree.

PRINT · SHARED KERNEL

Configure freely. Build once.

Rasterize once, assemble as often as you like — the boardroom handout is one tap away, on any paper.
