FIT LADDER · THE SPLIT MOVE

Auto-split

When a slide holds more than it can show, it becomes several — automatically, at export.

The problem auto-split solves

The problem auto-split solves

A slide holding fourteen things asks the reader to hold fourteen things

continues →

The problem auto-split solves (cont.)

Packed onto one page they **compete**; past the type floor there is nothing smaller to reach for

Below that floor the slide clips →

The problem auto-split solves (cont.)

Below that floor the slide **clips** — the title off the top, the last items off the bottom

continues →

The problem auto-split solves (cont.)

The honest fix is **more slides, not smaller type** — and **one thing on each**

How it works

How it works

A slide holding **more than one** structural element becomes one slide per element

continues →

How it works (cont.)

The trigger is **structure**, read from the markup — the cut is the same on every machine

continues →

How it works (cont.)

Every run opens on a **cover** and closes on the **note and key insight**

continues →

How it works (cont.)

Each page **points at the next one**, so the run reads as one thing

Read-across →

How it works (cont.)

Read-across content (columns, code) is **never split**

What you just saw

What you just saw

The fourteen-item checklist became a **cover, fourteen pages and a closing** — one check each

continues →

What you just saw (cont.)

The heading carried onto every page, marked `(cont.)`, and each page named **the next check**

continues →

What you just saw (cont.)

The author wrote one slide; the structure decided the rest

continues →

What you just saw (cont.)

Nothing was measured to get there, so the same deck cuts the same way on any machine

More slides, never smaller type

Readability is the floor
