Lattice · corners: rounded

The slide has a corner

One register, one token, and the brand bar comes with it.

What the register does

1. The engine owns the shape
   - `corners: rounded` in the deck's front matter, nowhere else
2. One rule owns how round
   - `section.corners-rounded`, and nothing downstream re-derives it
3. The deck decides, per deck
   - the same axis `theme:` and `color-mode:` already sit on

Why a clip and not a radius

The bar is a border image

and border images ignore `border-radius`

The clip cuts the whole element

so the bar hugs the corner too

Every edge placement follows

one property covers all four rails

Nothing inside needs a rule

the section already clips its children

Its rail rides the background

A divider rounds too

This slide opted out

1. `_class: corners-square`
   - a slide overrides the deck, the same way `_class: light` overrides a dark deck
2. The deck's token is evicted, not stacked
   - both rules land at one specificity, so leaving them side by side would let source order decide instead of the author

The export decides whether it survives

A corner is a hole

the slide stops painting, so something behind must show

PNG and WebP keep it

an alpha channel can carry a real hole

PDF and PPTX square it

a page is paper; a PPTX corner takes the reader's template

This very PDF is square

which is why you are reading a full-bleed page right now

Square is still the default

A deck that says nothing renders exactly as it did before this existed — and a rounded corner only reads where the slide's surface differs from what sits behind it.
