export · player · light-dark()

What the toggle used to leave behind.

The shared HTML player splits every dual-mode color at export time, because the CSS function it replaces does not exist on the engines this file has to open on. Two of the three places a color can hide were already covered. This deck is the third.

Sink one · box-shadow

A card's elevation is two recipes, not one.

LIGHT CANVAS

- Contact shadow, at 7% black
- Float shadow, at 8% black

DARK CANVAS

- Inset top rim, at 13% white
- Float shadow, at 32% black

EITHER CANVAS

- The idle layer paints clear

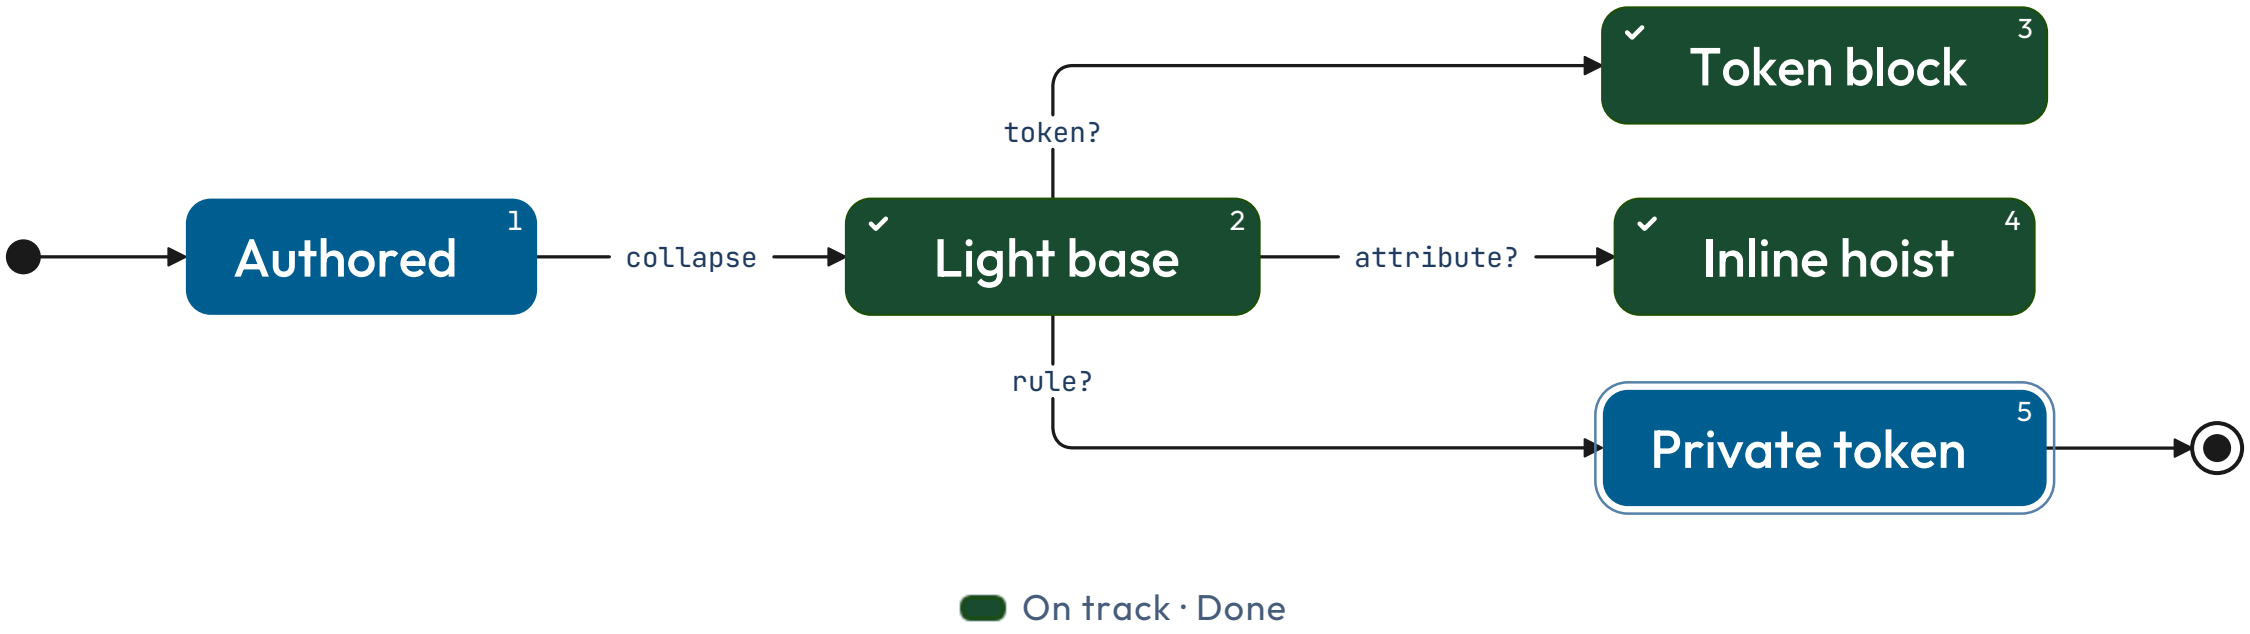

Sink two · background

Every fill mixes its hue into the canvas.

Pair to page

Where a color can hide, and which pass catches it.

The first two passes shipped earlier; the third is this change.

C

Sink three

Chrome sits on the rail, so it takes the rail's ink

Chrome ink · split-panel watermark

Why the header changed rung

1. **Curated**
   The rail's own ink, tuned per palette against that palette's accent.
2. **Derived**
   A 70% alpha of it — sub-AA on seven palettes, invisible on one.
3. **Recessive**
   Size and case carry the step down. The alpha was not doing that work.

Check the next sink on the real export, not in the text.

The contract, now true

Nothing the player ships depends on the function it replaces.

Each sink was invisible to the gate written for the one before it.
