Lattice · list-tabular

The ledger fits its own content.

Columns size to what is in them, and the deck says which column should absorb the slack.

What changed.

One set of tracks, shared by every row.

Each track sizes to its widest content.

A rule falls between rows, never above the first or below the last.

The ledger centers in the space it is given.

`fit-*` and `flex-*` name the column that absorbs.

Before: every label paid for the longest one.

01	ID	Two letters, a track sized for twenty.
02	Extraordinarily long row label that will not fit	Wraps three lines.
03	Mid	The same waste again.
04	Governance and control framework alignment	And again.

`fixed` is the pre-responsive behavior, kept as an opt-out.

After: the track is the widest label, once.

01	ID	Two letters take two letters.
02	Extraordinarily long row label that will not fit	One line.
03	Mid	Nothing is padded out.
04	Governance and control framework alignment	The column is content, not a guess.

The default. No modifier was added to this slide.

`flex-name` hands the leftover to the label.

01	Board approval of the revised treasury policy	Q3
02	Migration of the settlement ledger to the new engine	Q4
03	Retirement of the legacy reconciliation batch	Q1

When the label is the point and the clause is a short qualifier.

`fit-body` hugs the clause and holds the right edge.

01	**Settlement window**	Same day cutoff	T+1
02	**Reconciliation cadence**	Automated	NIGHTLY
03	**Exception review**	Risk committee	WEEKLY

The trailing column takes the slack, so it never strands itself mid-slide.

Every variant inherits the same tracks.

01	api	STABLE
02	cli	STABLE
03	sdk	BETA
04	web	PREVIEW

`register` — the pills sit at the right edge instead of a fixed 0.9fr column.

One set of tracks, shared by every row

The columns are the content.

The default fits — most ledgers need no modifier at all.

`fit-name` `fit-body` `fit-meta` hug one column.

`flex-name` `flex-meta` name the column that absorbs.

`fixed` keeps a deck that was tuned around the old widths.
