ep-curve

An exceedance-probability curve: the loss to expect once every N years, with return periods across on a log scale and up to four curves (OEP and AEP, gross and net).

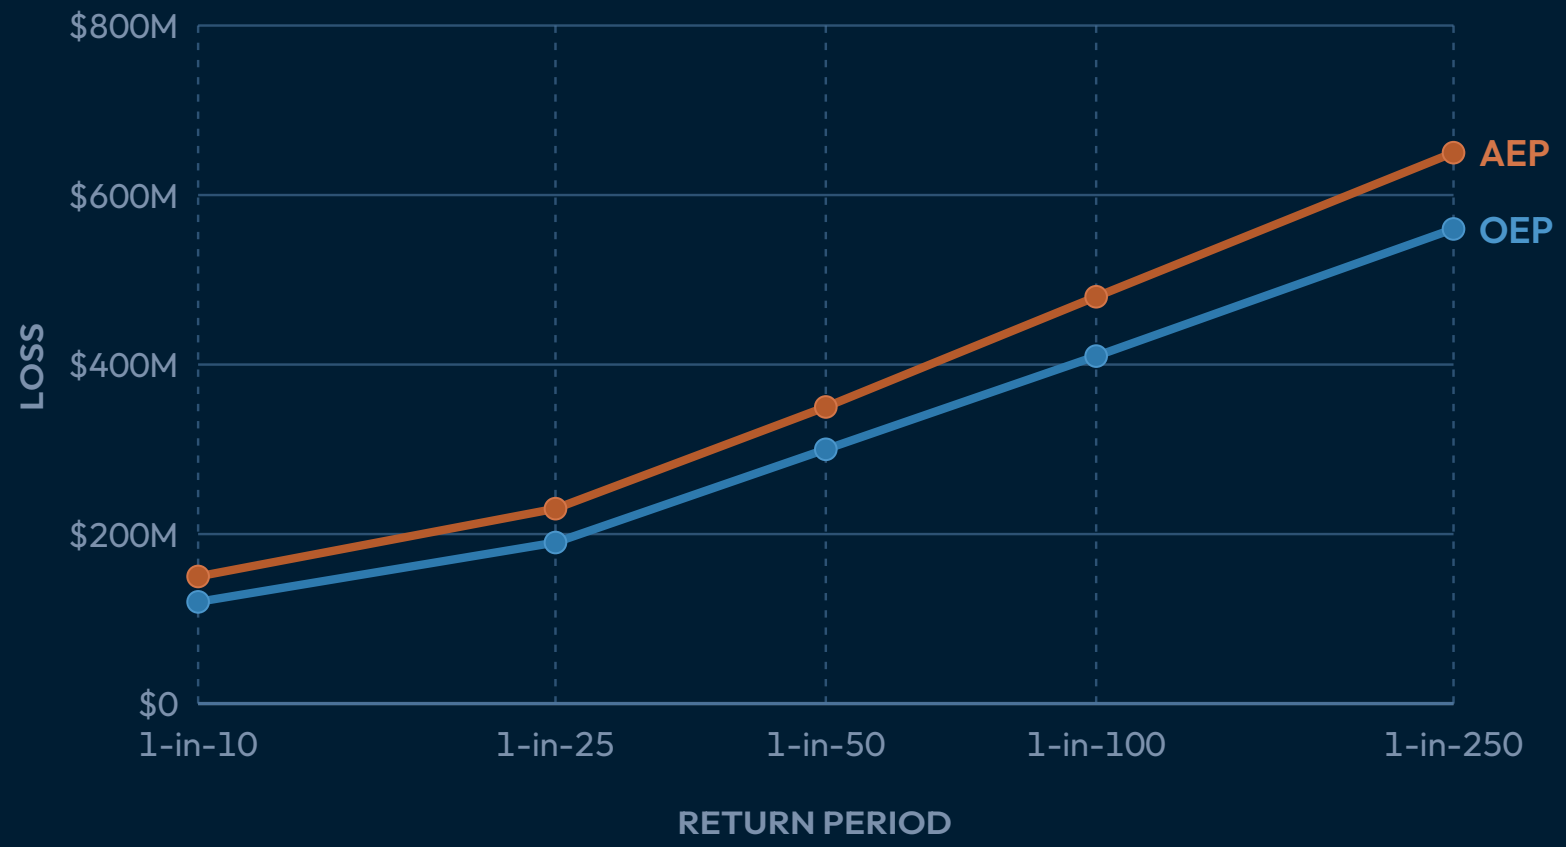

A 1-in-100 year costs $410M a single event, $480M a year.

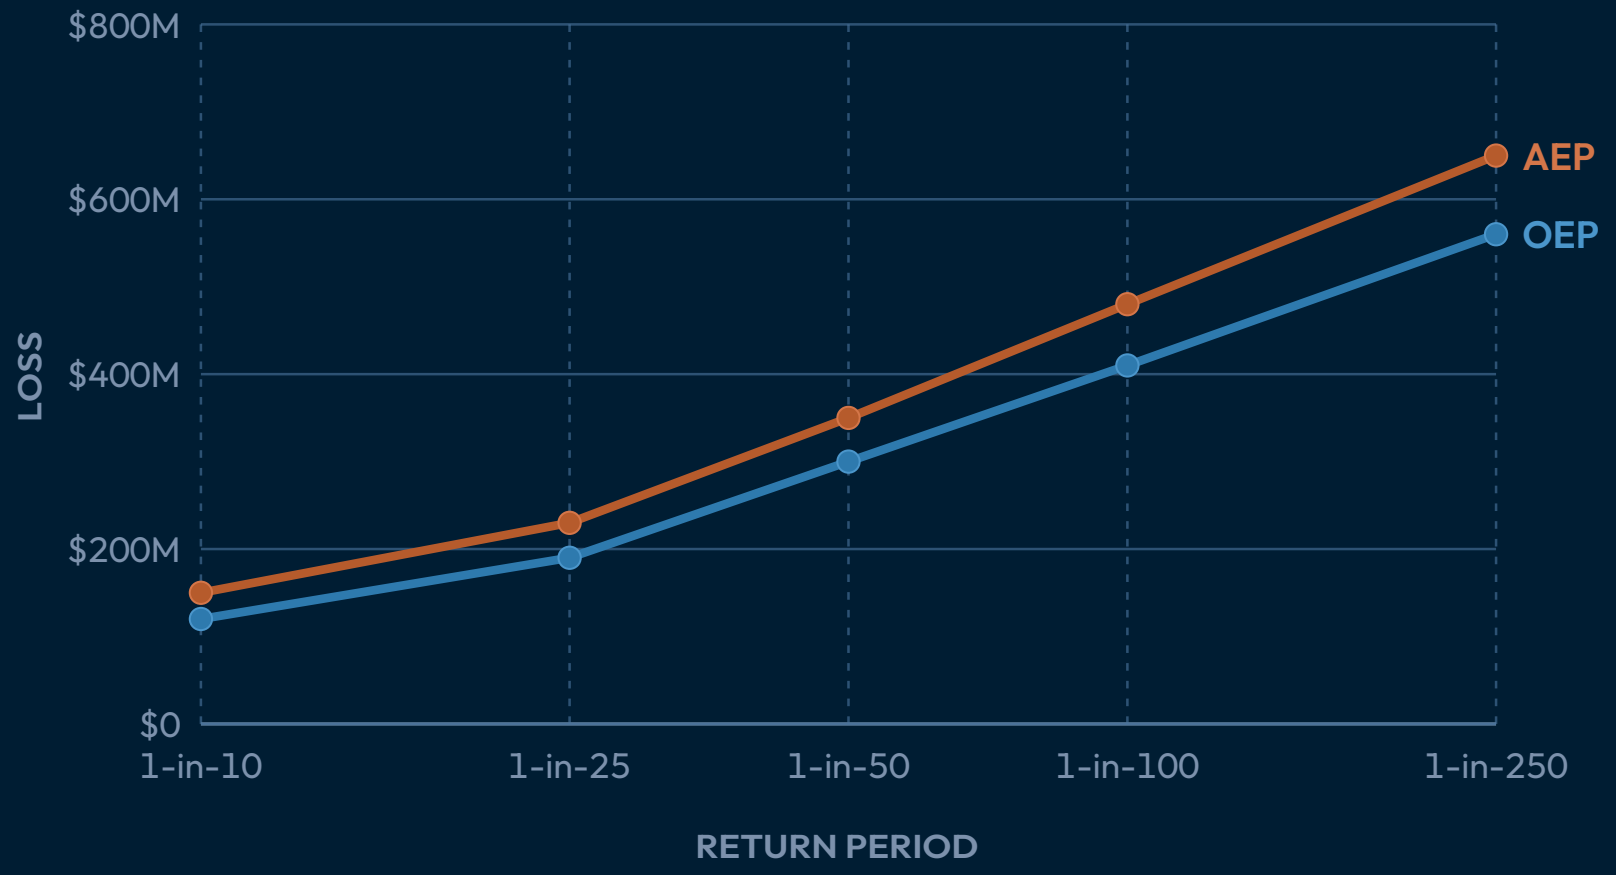

Four curves, eight return periods.

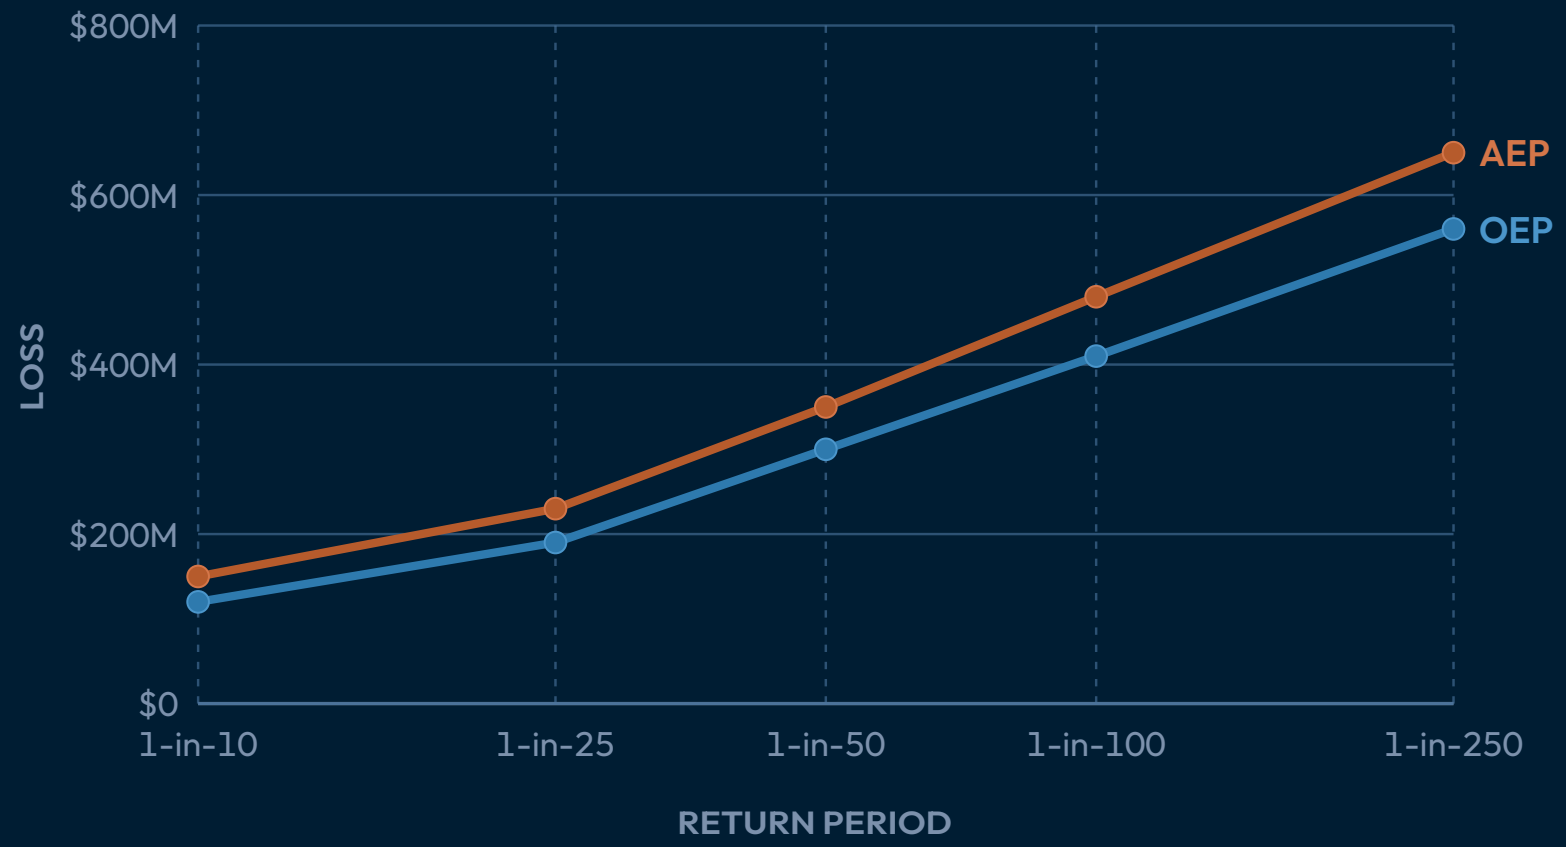

A 1-in-100 year costs $410M a single event, $480M a year.

A 1-in-100 year costs $410M a single event, $480M a year.

A 1-in-100 year costs $410M a single event, $480M a year.

Composition: accent · ep-curve accent

When NOT to reach for ep-curve.

Return period written as a label

`- 1-in-100` $410M `is a label and a value, which the chart cannot place. Write the point record, return period first:` `{100, $410M}` ``; the axis prints `1-in-100` for you.

A probability instead of a return period

Write the return period, not the annual probability: 1% is `{100, …}`, 0.4% is `{250, …}`.
