

LATTICE • PORTRAIT PROSE DE-BOOST

# Dense layouts that fit the tall frame.

The same content-dense layouts, on a 9:16 frame. Body prose de-boosts so the title and last item stay on the slide — hero type keeps its presence.

# The framework has four components.

Signal Intake →

# The framework has four components.

---

## Signal Intake

Weekly structured collection across conversations, market data, and competitive moves.

# The framework has four components. (cont.)

## Scoring Model

Each signal scored on confidence, recency, and relevance. Weights reviewed quarterly.

# The framework has four components. (cont.)

---

## Decision Log

Every decision recorded with the signals that informed it and the criteria applied.

# The framework has four components. (cont.)

---

## Calibration Loop

Monthly retrospective comparing predicted to actual outcomes, adjusting the weights.

# Who owns each part of the lifecycle.

Signal custody →

# Who owns each part of the lifecycle.

---

## Signal custody

Signal owner

Runs intake quality. Never tunes the weights — only picks which signals surface.

Policy →

# Who owns each part of the lifecycle. (cont.)

## Policy

Framework operator

Owns scoring policy, calibration cadence, and the rollback playbook. One person.

Consumption →

# Who owns each part of the lifecycle. (cont.)

## Consumption

Product team

Holds scoring profiles; runs intake and decision-logging; finds the bugs first.

# Who owns each part of the lifecycle. (cont.)

## Oversight

Auditor

Reads the audit trail, cannot edit weights, and is the only role anyone fears.

# Four failure modes the framework prevents.

False signal amplification →

# Four failure modes the framework prevents.

---

## False signal amplification

One loud voice dominates the decision.  
The model caps any single source at 30% of weight.

# Four failure modes the framework prevents. (cont.)

---

## Signal hoarding

Teams collect signals but never log decisions, so the calibration loop has nothing to learn from.

# Four failure modes the framework prevents. (cont.)

---

## Recency bias drift

The newest signal feels most urgent; without recency weighting it overrides calibrated history.

Confidence inflation →

# Four failure modes the framework prevents. (cont.)

---

## Confidence inflation

Owners self-mark signals high-confidence; the model audits that against realized outcomes.

# Signal value versus effort to capture.

Quadrant by quadrant →

# Signal value versus effort to capture.

---

## High value, low effort

Win/loss interviews. Already happening; just needs structured capture.

# Signal value versus effort to capture. (cont.)

---

## High value, high effort

Longitudinal cohort tracking. Worth it, but staff it deliberately.

# Signal value versus effort to capture. (cont.)

---

## Low value, low effort

Sentiment tags. Cheap to collect, rarely change a decision.

# Signal value versus effort to capture. (cont.)

---

## Low value, high effort

Open-ended surveys. Expensive to analyze, low signal density.

# What we recommend, and why.

The reasoning →

What we recommend, and why.

---

# Build

Full control, but 2–3 engineer-quarters and ongoing maintenance.

Buy →

What we recommend, and why.

---

# Buy

Ship in 6 weeks; redirect engineering to product-layer features.

Partial →

What we recommend, and why.

---

# Partial

Hybrid splits ownership and doubles the integration surface.

Defer →

What we recommend, and why.

---

## Defer

Costs a quarter of signal data we can never reconstruct later.

# The scoring model, before and after calibration.

Side by side →

The scoring model, before and after calibration.

---

## **Before calibration**

Equal weights across all three dimensions. Confidence, recency, and relevance each contribute 33%. Simple and consistent, but blind to what your market rewards.

After calibration →

## After calibration

Weights reflect your team's historical accuracy. If recency has been the weakest predictor, it gets downweighted. The model becomes a record of what you have learned.

the note →

The scoring model, before and after calibration.

---

The shift takes two retrospective cycles to stabilize.

# Build the data layer or buy it?

Both paths are viable. The difference is where we spend the next 18 months.

The choice →

# Build the data layer or buy it?

## BUILD IN-HOUSE

---

- Full control over schema and roadmap
- 2–3 engineer-quarters to feature parity
- Ongoing maintenance stays internal

# Build the data layer or buy it?

## BUY + CONFIGURE

- Ship in 6 weeks, not 9 months
- Engineering redirects to product features
- Exit risk manageable via data export

the key insight →

Build the data layer or buy it?

**KEY INSIGHT**

Buy the infrastructure. Build the differentiation.

LATTICE • PORTRAIT PROSE DE-BOOST

Hero type stays;  
dense prose adapts.
