

A state machine that branches.

The numbered column is kept for chains. A fan-out gets a real graph layout.

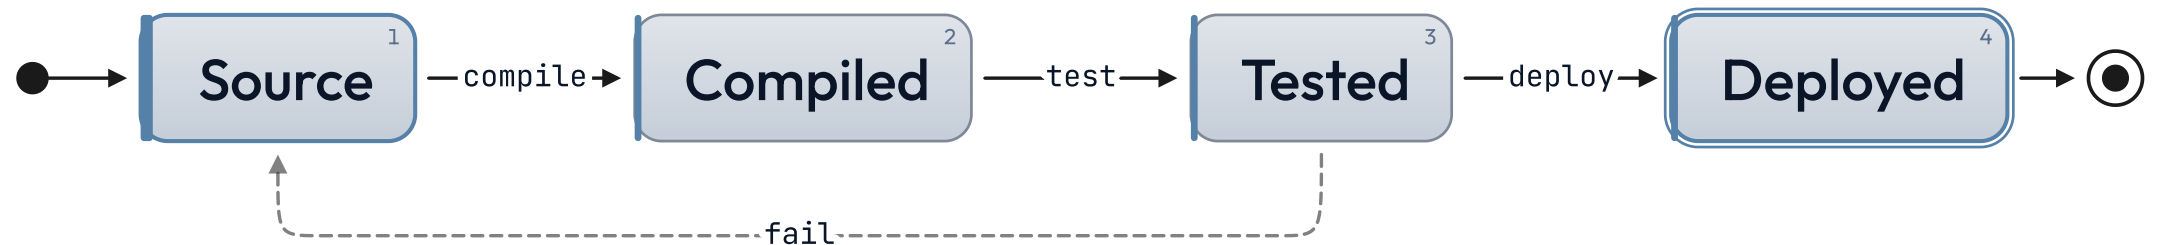

The rule

A chain keeps *state i at row i* . A machine that branches is re-ranked.

CHAIN

A chain is unchanged.

One outgoing edge per state — the column already is the right answer.

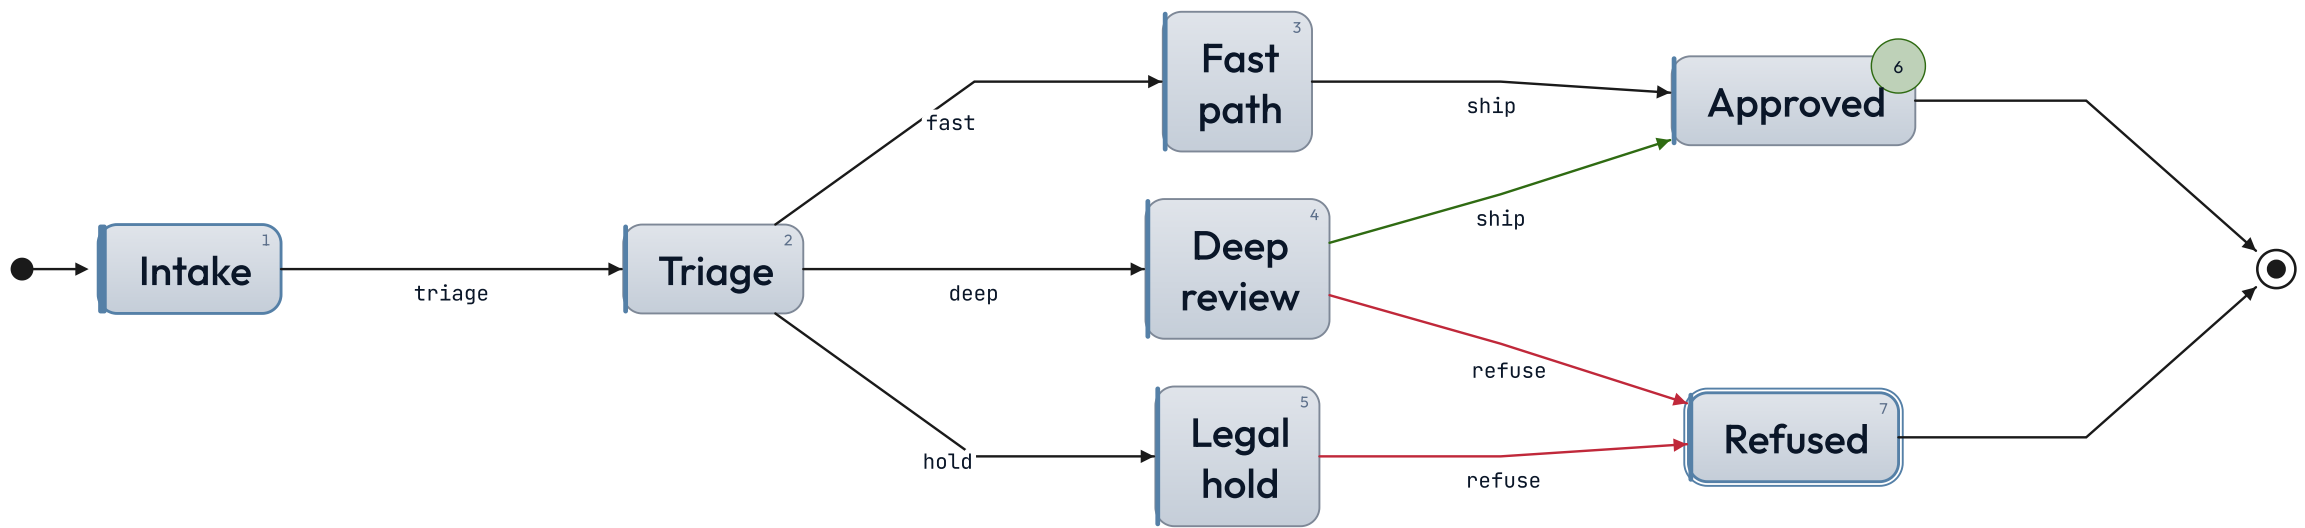

Every machine in the six shipped galleries lays out exactly as it did before.

FAN-OUT

Three ways out of one state.

No single column can show this; the states would read as a sequence.

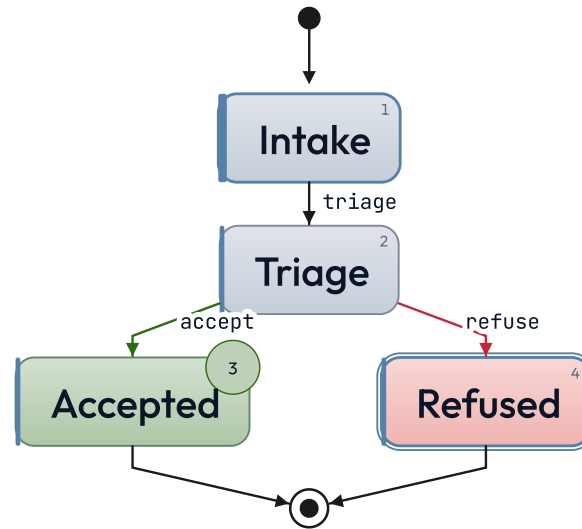

The numbering still names each state; it just no longer dictates the row.

● done

TOP TO BOTTOM

The same machine, stacked.

Direction is still the author's call — lr or the default.

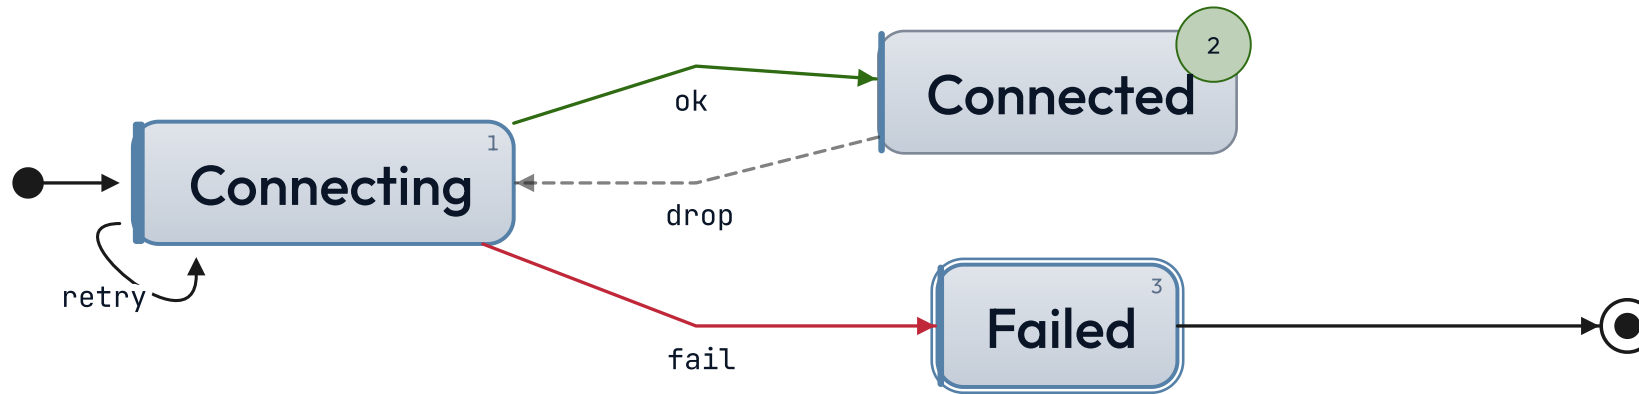

Terminal states converge on one exit marker, ranked with everything else.

● done

SELF-LOOPS

A self-transition still routes the old way.

dagre does not route a self-edge, so the hand-written router keeps drawing them.

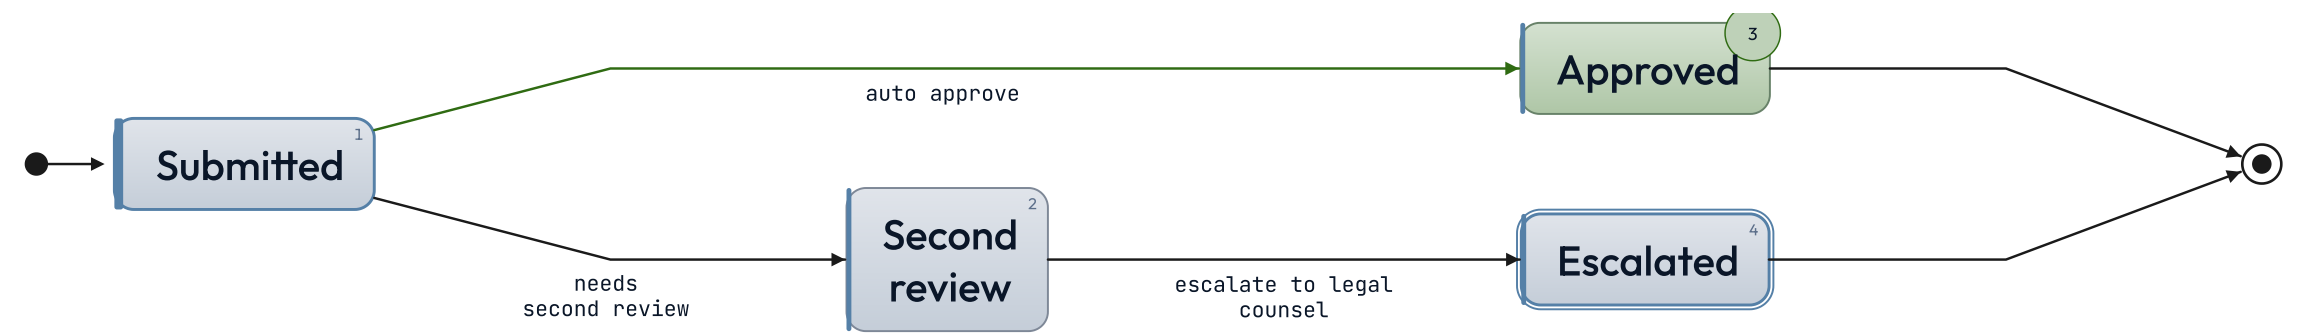

One machine, two routers – whichever is right for each edge.

● live

LONG LABELS

A label can break, or wrap itself.

`\n` and `<br/>` break where you say; anything still too long wraps on its own.

Labels sit below the line on

```
lr
```

and to the right on the default, so a two-line label never punches a hole through the edge it belongs to.
